Fishing Line Diameters

Over 5,000 saltwater fishing links
Come on in. The water's fine!

[Fishing Line Page](#)[Home](#)

Welcome to Mel's 2016 Fishing Line Diameter page

The line diameter tables below offer a comparison of more than 100 popular monofilament, copolymer, fluorocarbon fishing lines and braided superlines in tests from 6-pounds to 600-pounds

If you like what you see, download a copy

You can also visit our [Fishing Line Page](#) for more information and links to line manufacturers. The line diameters shown are compiled from manufacturer's web sites, product catalogs and labels on line spools.

Background Information

When selecting a fishing line, one must consider a number of factors. While knot strength, abrasion resistance, suppleness, shock resistance, castability, stretch and low spool memory are all important characteristics, the diameter of a line is probably the most important. As long as these other characteristics meet your satisfaction, then the smaller the diameter of the line the better. With smaller diameter lines: more line can be spooled onto the reel, they are usually less visible to the fish, will generally cast better, and provide better lure action.

Line diameter measurements provided by manufacturers are expressed in thousandths of an inch (0.001 inch) and its metric system equivalent, hundredths of a centimeter (0.01 centimeter). However, not all manufacturers provide line diameter information, so if you don't see it in the tables, that's the likely reason why. And some manufacturers now provide line diameter measurements in ten-thousandths of an inch (0.0001 inch) and thousandths of a centimeter (0.001 centimeter). To give you an idea of just how small this is, one ten-thousandth of an inch is less than 3% of the diameter of an average human hair. A ten-thousandth of an inch may be tiny and difficult to measure accurately, but it certainly has marketing value if it allows you to say you have the smallest diameter fishing line.

There is no industry standard for measuring fishing line diameters and line manufacturers do not divulge how they measure their lines. Digital calipers and micrometers provide reasonably accurate measurements of solid, round monofilament, copolymer and fluorocarbon fishing lines. However, braided lines are not solid and will compress when these instruments apply pressure to get a reading. Diameter readings of braided lines can be made, but the line has to be under tension so it will not deform. The question is how much tension to apply since it will change the line's diameter. In addition, some braided lines have cross sections that are not circular; they are flattened or elliptical and that also makes measurement challenging.

Nylon-based monofilament lines are popular fishing lines that became widely available in the late 1950s. They are made using an extrusion process by melting and mixing nylon polymers and then pushing it through a die which forms the solid and round strand of monofilament. They are usually inexpensive and come in a wide variety of sizes and special formulations for just about any kind of fishing you can think of.

Fluorocarbon lines and leaders provide an added advantage when pursuing line-shy fish. Fluorocarbon line is made with the same die extrusion process as standard monofilaments, but from the fluoropolymer polyvinylidene fluoride (PVDF). Fluorocarbon lines have a refractive index very close to that of saltwater; in other words, when you put it in saltwater it is almost invisible to fish. It is also a denser material and does not absorb water, so it sinks faster than monofilament lines; and unlike monofilament, does not lose its strength when wet. Fluorocarbon lines are also very abrasion resistant, but it is stiff and knots can be harder to tie properly especially with heavier weight lines. While competition has dropped prices, fluorocarbon lines and leaders still cost more than regular monofilament.

Copolymer lines became commercially available in the early 1980s. Copolymer lines are also made with the same die extrusion process as standard monofilaments. The difference is that two or more types of nylons with different characteristics are merged during the extrusion to form a single copolymer strand. The resulting copolymer line has many advantages over traditional nylon monofilament lines. They have smaller line diameters, are more abrasion resistant, have lower stretch, a higher tensile strength, and a higher impact and shock resistance than standard monofilaments. New formulas, such as the addition of fluorocarbon add invisibility to the line. But once again, it can be a bit more expensive

than standard monofilament.

Braided superlines became commercially available in the early 1990s. They have taken over by storm and not many folks saw it coming. Regardless of their trade name and composition (Spectra® or Dyneema®), braided superlines are all made from gelspun ultra-high-molecular-weight polyethylene (UHMWPE, HMPE) fibers that are braided together.

They are much thinner than monofilament lines and that allows you to put a lot more line on your reel. This is especially handy when you are rigging up for large game fish, such as tuna, that can strip lots of line from your reel. Superlines have very little stretch and while this is good for certain kinds of fishing (such as bottom fishing in deep water); they are unforgiving when you get a large fish close to the boat (you can easily pull the hook out.) The superlines are also very limp and unlike monofilaments, are very resistant to damage from sunlight (they last a long time.) Due to their lack of stretch, flexibility and a slippery surface, superlines are hard to knot properly and only certain knots hold well. However, the advantages of braided superlines don't come cheap; expensive raw materials and a slow and complicated manufacturing process make braided lines more expensive. They are by far, the most expensive fishing lines on the market.

Since most braided fishing superlines are based on either Dyneema® or Spectra® fibers, they all have the same basic properties. It's how you braid and process the fibers that dictate the performance of the finished line. To change the properties of their braided superlines, manufacturers can vary the number of fibers in the braid, the size of the fibers, the angle of the fibers during braiding, the tension of the fibers during braiding, the addition of special coatings, the incorporation of other types of fibers, and thermally or chemically fusing the braid. It all depends on the kind of fishing that the line is being made for.

The line diameters shown below are compiled from manufacturer's web sites, product catalogs and labels on line spools.

Test in lbs.	Inch	mm	Brand	Line Type
6	0.002	0.051	McCoy Super Braid - braided Spectra line	Braid
